Abstract

We prove NP-hardness and #P-hardness of Tetris clearing (clearing an initial board using a given sequence of pieces) with the Super Rotation System (SRS), even when the pieces are limited to *any two* of the seven Tetris piece types. This result is the first advance on a question posed twenty years ago: which piece sets are easy vs. hard? All previous Tetris NP-hardness proofs used five of the seven piece types. We also prove ASP-completeness of Tetris clearing, using three piece types, as well as versions of 3-Partition and Numerical 3-Dimensional Matching where all input integers are distinct. Finally, we prove NP-hardness of Tetris survival and clearing under the “hard drops only” and “20G” modes, using two piece types, improving on a previous “hard drops only” result that used five piece types.

We thank the other participants of that class for helpful discussions and providing an inspiring atmosphere. Figures drawn with SVG Tiler (<https://github.com/edemaine/svgtiler>).

1 Introduction

Tetris is one of the oldest and most popular puzzle video games, originally created by Alexey Pajitnov in 1984. Tetris has reached mainstream media many times, most recently in the biopic *Tetris* [1] and with the news of 13-year-old Willis Gibson being the first person to “beat” the NES version of Tetris by reaching a killscreen [6].

The rules of Tetris are simple. In each round, a tetromino piece (one of , , , , , , ) spawns at the top of a grid and periodically moves down one unit, assuming the squares below the piece are empty. The player can repeatedly move this piece one unit left, one unit right, or one unit down, or rotate the piece by $\pm 90^\circ$. When any part of the piece rests on top of a filled square for long enough that it triggers an automatic downward move, the piece “locks” in place, and stops moving. If a piece stops above a certain height or where the next piece would spawn, the player loses; otherwise, the next

Table 1 Our NP-hardness results for Tetris clearing assuming SRS. Each entry in a specific row and column corresponds to the proposition for the hardness of the two-element subset consisting of the row piece and column piece (for example, the entry “Prop. 6” in row and column indicates that Proposition 6 proves hardness for the subset $\{\text{cyan 1x4 piece}, \text{yellow 2x2 piece}\}$). Letters in parentheses denote additional models (“H” for “hard drop only”, “G” for “20G”); question mark indicates a conjecture for hardness under that additional model.

40 piece spawns at the top of the grid, and play continues. Completely filling a row causes the
 41 row to clear, and all squares above that row move downward by one unit. For more detailed
 42 rules, see [16].

43 To study Tetris from a computational complexity perspective, we generally assume that
 44 the player is given a sequence of pieces and an initial board state of filled cells, making the
 45 game perfect information (as introduced in [4]). The two main objectives we consider here are
 46 “clearing” and “survival” (as introduced in [7]). In *Tetris clearing*, we want to determine
 47 whether we can clear the entire board after placing all the given pieces. In *Tetris survival*,
 48 we want to determine whether the player can avoid losing before placing all the given pieces.
 49 Previous work shows that these problems are NP-complete, even to approximate various
 50 metrics within $n^{1-\epsilon}$ [4], or with only 8 columns or 4 rows [2], or with additional constraints
 51 on drops [12], or with k -ominoes for $k \geq 3$ clearing or $k \geq 4$ survival [7].

52 1.1 Our Results

53 One of the open problems posed in the original paper proving Tetris NP-hard twenty years
 54 ago [4] is to determine which subsets of the seven Tetris piece types $\{\text{cyan 1x4 piece}, \text{yellow 2x2 piece}, \text{purple T piece}, \text{green 2x2 piece},$
 55 $\text{red 2x2 piece}, \text{blue L piece}, \text{orange 2x2 piece}\}$ suffice for NP-hardness, and which admit a polynomial-time algorithm. All
 56 existing Tetris NP-hardness proofs [4, 2, 12] use at least five of the seven piece types. In
 57 particular, [4, Section 6.2] mentions various sets of five piece types that suffice. What about
 58 fewer piece types?

59 Our main results are the first to make progress on this question: for any *size-2* subset
 60 $A \subseteq \{\text{cyan 1x4 piece}, \text{yellow 2x2 piece}, \text{purple T piece}, \text{green 2x2 piece}, \text{red 2x2 piece}, \text{blue L piece}, \text{orange 2x2 piece}\}$, Tetris clearing is NP-complete with pieces
 61 restricted to A . Most pairs of piece types require different constructions for their reductions;
 62 refer to Table 1. Our results require us to specify more details of the piece rotation model,
 63 specifically what happens when the player rotates a piece in a way that collides with a filled
 64 square. We assume the *Super Rotation System (SRS)* [14], first introduced in the 2001
 65 game *Tetris Worlds* and as part of the Tetris Company’s Tetris Guideline for how all modern
 66 (2001+) Tetris games should behave [15].

67 For every size-2 subset A of piece types, we also establish #P-hardness for the corres-
 68 ponding problem of counting the number of ways to clear the board. Here we distinguish
 69 solutions by the final placement of each piece, not the sequence of moves to make those
 70 placements (as long as the placement is valid). This definition lets us ignore e.g. the null
 71 effect of moving a piece repeatedly left and right.

For certain size-3 subsets of piece types, we further establish ASP-completeness for Tetris clearing. Recall that an NP search problem is *ASP-complete* [17] if there is a parsimonious reduction from all NP search problems (including a polynomial-time bijection between solutions). In particular, ASP-completeness implies NP-hardness of finding another solution given k solutions, for any $k \geq 0$, as well as #P-completeness. These results hold for piece types $\{\text{cyan}, \text{purple}, \text{orange}\}$ and $\{\text{cyan}, \text{purple}, \text{blue}\}$.

We also study Tetris under two more restrictive models on piece moves:

- **Hard drops only:** In this model, pieces do not move downward on their own, and if the player moves a piece downward, the piece moves maximally downward before locking into place (a *hard drop* maneuver). The player is still free to rotate or move the piece left or right before hard-dropping the piece. This model is motivated by most Tetris games awarding higher scores for hard drops, and was posed in [4].
- **20G:** In this model, instead of periodically moving down one unit, all pieces move maximally downward *instantly and on their own*, and the player is not allowed to control how fast a piece moves downward. The player is still free to rotate or move the piece left or right before the piece locks. This model is motivated by levels with the maximum possible gravity, as in Level 20+ of regular Tetris with 20 rows [13].

For certain size-2 subsets of piece types, we establish NP-hardness of both Tetris survival and clearing under either of these models. Table 1 labels which of our Tetris clearing results hold in which models.

Along the way, we prove new results about 3-Partition and Numerical 3-Dimensional Matching (3DM): both problems are strongly ASP-complete even when all integers are assumed distinct. These results are of independent interest for ASP-hardness reductions. Previously, these problems were known to be ASP-complete with multisets of integers [3], and strongly NP-complete with distinct integers [10].

1.2 Outline

The structure of the rest of the paper is as follows. Section 2 details the Super Rotation System (SRS), an important aspect of modern Tetris and used in our constructions. Section 3 proves ASP-completeness of 3-Partition with Distinct Integers and Numerical 3-Dimensional Matching with Distinct Integers, two problems we reduce from. Section 4 discusses our hardness results for Tetris clearing with SRS with only two piece types. Section 5 discusses some Tetris survival results under the “hard drops only” and “20G” models. Section 6 proves ASP-completeness of Tetris clearing with SRS.

2 Super Rotation System (SRS)

Most previous Tetris results are not sensitive to exactly how Tetris pieces rotate: most reasonable rotation models work [4, Section 6.4]. By contrast, many of the results in this paper focus specifically on (and require) the *Super Rotation System (SRS)* [14], defined as follows.

Each piece has a defined *rotation center*, as indicated by dots in Figure 1, except for  and , whose rotation centers are the centers of the 4×4 squares in Figure 1. When unobstructed, all non- tetrominoes will rotate purely about the rotation center (note that  pieces cannot rotate). The key feature about SRS is *kicking*: if a tetromino is obstructed when a rotation is attempted, the game will attempt to “kick” the tetromino into one of four alternate positions, each tested sequentially; if all four positions do not work,

12:4 Tetris with Few Piece Types

116 then the rotation will fail. See Figure 2 for an example of this kicking process. The full data
 117 for wall kicks can be found in Tables 2 and 3, and at [14]. Of note is that SRS wall kicks
 118 are vertically symmetric for all pieces or pairs of pieces (i.e.,  \leftrightarrow  and  \leftrightarrow )
 119 except for the  piece, so all rotations can be mirrored.

Figure 1 All tetromino pieces, in order from top to bottom: , , , , , , . The first column is the default orientation of a piece upon spawning in; each column to the right indicates a 90° rotation clockwise about the rotation center of the piece.

Figure 2 An example of the SRS kick system. Suppose the  piece in (a) is being rotated 90° counter-clockwise. Test 1 (which is (0,0)) would fail, due to the dark gray square shown in (b). Test 2 (which is (+1,0)) would succeed, as shown in (c), and so the  piece would rotate to the position in (c).

120 This system of kicking tetrominoes during rotations allows for moves which are often
 121 called *twists* or *spins*. All the spins that we utilize are detailed in the appendix of the full
 122 version of our paper.

123 **3** 3-Partition and Numerical 3DM with Distinct Integers

124 Our reductions to Tetris are all from one of the following two problems, which are strength-
 125 enings of two standard strongly NP-complete problems:

126 **► Definition 1 (3-Partition with Distinct Integers).** Given a set $A = \{a_1, a_2, \dots, a_n\}$ of n
 127 *distinct* positive integers such that $\frac{t}{4} < a_i < \frac{t}{2}$ for each i , where $t = \frac{3}{n} \sum_{i=1}^n a_i$, determine
 128 whether there is a partition of A into $\frac{n}{3}$ groups $D_1, \dots, D_{n/3}$ (each necessarily of size 3)
 129 having the same sum $\sum_{x \in D_j} x = t$.

	Test 1	Test 2	Test 3	Test 4	Test 5
$0 \rightarrow R$	(0, 0)	(-1, 0)	(-1, +1)	(0, -2)	(-1, -2)
$R \rightarrow 0$	(0, 0)	(+1, 0)	(+1, -1)	(0, +2)	(+1, +2)
$R \rightarrow 2$	(0, 0)	(+1, 0)	(+1, -1)	(0, +2)	(+1, +2)
$2 \rightarrow R$	(0, 0)	(-1, 0)	(-1, +1)	(0, -2)	(-1, -2)
$2 \rightarrow L$	(0, 0)	(+1, 0)	(+1, +1)	(0, -2)	(+1, -2)
$L \rightarrow 2$	(0, 0)	(-1, 0)	(-1, -1)	(0, +2)	(-1, +2)
$L \rightarrow 0$	(0, 0)	(-1, 0)	(-1, -1)	(0, +2)	(-1, +2)
$0 \rightarrow L$	(0, 0)	(+1, 0)	(+1, +1)	(0, -2)	(+1, -2)

■ **Table 2** Kick data for , , , , and  pieces. 0 indicates the default orientation, and R , 2, and L indicate the orientation reached from a 90° , 180° , and 270° rotation clockwise (respectively) from the default orientation. An ordered pair (a, b) denotes a translation of the center by a units in the x direction and b units in the y direction. Positive x direction is rightwards, and positive y direction is upward.

	Test 1	Test 2	Test 3	Test 4	Test 5
$0 \rightarrow R$	(0, 0)	(-2, 0)	(+1, 0)	(-2, -1)	(+1, +2)
$R \rightarrow 0$	(0, 0)	(+2, 0)	(-1, 0)	(+2, +1)	(-1, -2)
$R \rightarrow 2$	(0, 0)	(-1, 0)	(+2, 0)	(-1, +2)	(+2, -1)
$2 \rightarrow R$	(0, 0)	(+1, 0)	(-2, 0)	(+1, -2)	(-2, +1)
$2 \rightarrow L$	(0, 0)	(+2, 0)	(-1, 0)	(+2, +1)	(-1, -2)
$L \rightarrow 2$	(0, 0)	(-2, 0)	(+1, 0)	(-2, -1)	(+1, +2)
$L \rightarrow 0$	(0, 0)	(+1, 0)	(-2, 0)	(+1, -2)	(-2, +1)
$0 \rightarrow L$	(0, 0)	(-1, 0)	(+2, 0)	(-1, +2)	(+2, -1)

■ **Table 3** Kick data for  pieces, with same notation as Table 2.

► **Problem 2 (Numerical 3-Dimensional Matching (3DM) with Distinct Integers).** *Given three sets*

$$A = \{a_1, a_2, \dots, a_n\}, B = \{b_1, b_2, \dots, b_n\}, \text{ and } C = \{c_1, c_2, \dots, c_n\}$$

130 of n positive integers, where all $3n$ integers are **distinct**, and a target sum $t = \frac{1}{n} \sum_{i=1}^n (a_i +$
 131 $b_i + c_i)$, determine whether there is a partition of $A \cup B \cup C$ into n groups D_1, \dots, D_n , each
 132 with exactly one element from each of A , B , and C , and $\sum_{x \in D_j} x = t$ for all j .

133 Without the “distinct” and “set” conditions, both problems are well-known to be **strongly**
 134 **NP-complete**, meaning that the problem is NP-hard even if the a_i integers are bounded by
 135 a polynomial in n . This property makes it feasible to represent each integer a_i (and t) in
 136 unary, which is the approach taken by all past Tetris NP-hardness proofs [4, 7, 2, 12], as
 137 then the total reduction size is still polynomial in n .

138 We want to ensure all integers are distinct in order to have more control over our reductions’
 139 blowup in the number of solutions, as needed for #P- and ASP-hardness. Bosboom et al. [3]
 140 proved that numerical 3DM is strongly ASP-complete when A is restricted to be a set, but
 141 allowed for B and C to be multisets as usual, and did not forbid repeated integers between
 142 A, B, C . Hulett, Will, and Woeginger [10] proved that both 3-Partition and Numerical
 143 3DM remain strongly NP-hard with distinct integers. We extend their proof to obtain
 144 ASP-completeness:

145 ► **Theorem 3.** *3-Partition with Distinct Integers, and Numerical 3-Dimensional Matching*
 146 *with Distinct Integers, are strongly ASP-complete.*

147 To prove this result, we use the following intermediate problems (which are thus also
 148 ASP-complete):

149 ► **Problem 4 (Positive 1-in-3SAT).** *Given a boolean formula in 3CNF (i.e., an AND of*
 150 *clauses consisting of 3 literals), where all literals are positive, does there exist an assignment*
 151 *of the variables to either true or false such that each clause has exactly one literal set to true?*

152 ► **Problem 5 (Tripartite Edge-Disjoint Triangle Partition).** *Given an undirected tripartite*
 153 *graph $G = (V, E)$, can we partition E into disjoint triangles?*

154 **Proof of Theorem 3.** We give a chain of parsimonious reductions from 3SAT, which is
 155 known to be ASP-complete [17]:

156 **1. 3SAT \rightarrow Positive 1-in-3SAT:** Hunt, Marathe, Radhakrishnan, and Stearns [11, The-
 157 orem 3.8] gave such a parsimonious reduction.² See also [3, Lemma 2.1].

158 **2. Positive 1-in-3SAT \rightarrow Tripartite Edge-Disjoint Triangle Partition:** We follow
 159 a simplification of a reduction from FCP 1-in-3SAT to FCP Tripartite Edge-Disjoint
 160 Triangle Partition [8, Theorem 12], which in turn is based on a reduction from 3SAT to
 161 Tripartite Edge-Disjoint Triangle Partition [9]. By reducing from Positive 1-in-3SAT, we
 162 simplify the reduction of [8] by avoiding negative literals.

163 We represent each variable by a sufficiently large triangular grid of vertices, with opposite
 164 sides of a parallelogram identified to form a flat torus, as shown in Figure 3a. This grid
 165 has exactly two solutions, corresponding to true (the triangles in Figure 3a) and false
 166 (the triangles in Figure 3b); note that the two solutions consist of exactly the same edges,
 167 and cover each exactly once. For each clause (x, y, z) , we pick one triangle of positive
 168 orientation, remove its edges, and unify the corresponding vertices of these triangles and
 169 of the three neighboring triangles of negative orientation, as shown in Figure 3c. Exactly
 170 one variable must choose the true state so as to cover the edges surrounding the unified
 171 hole exactly once. By choosing the variable gadgets large enough, we can ensure that the
 172 clause gadgets are disjoint from each other. Each gadget has a unique way to implement
 173 a given assignment, so this reduction is parsimonious.

174 **3. Tripartite Edge-Disjoint Triangle Partition \rightarrow Numerical 3DM with Distinct**
 175 **Integers:** We combine a chain of reductions, from Triangle Edge-Disjoint Triangle
 176 Partition to Latin Square Completion [5], and from Latin Square Completion to Numerical
 177 3DM with Distinct Integers [10].

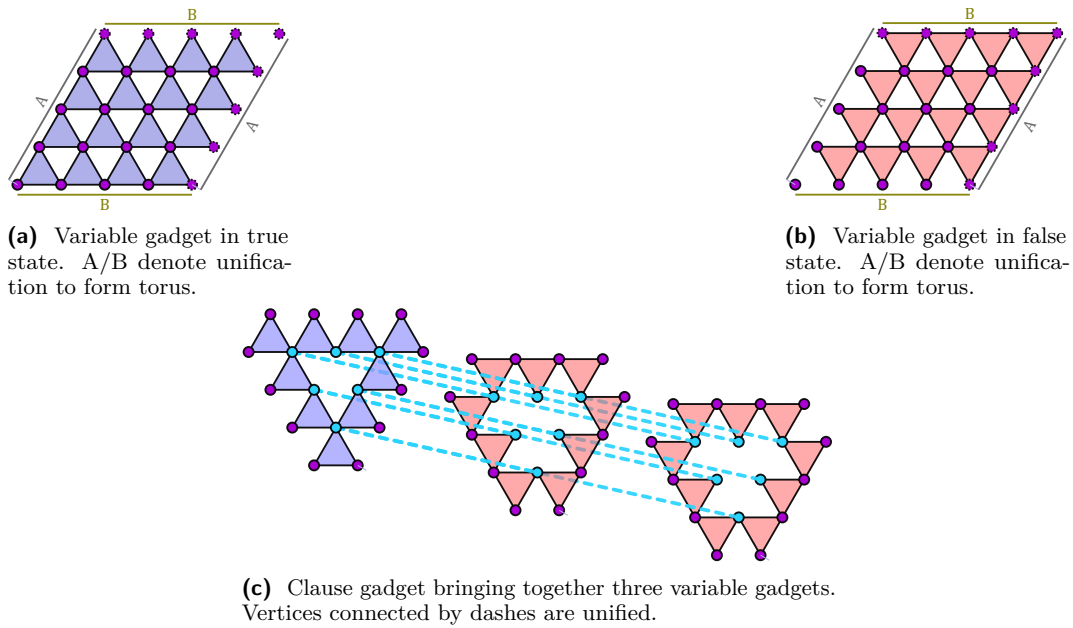

178 If $U = \{u_1, u_2, \dots\}$, $V = \{v_1, v_2, \dots\}$, $W = \{w_1, w_2, \dots\}$ is the vertex tripartition, then
 179 we do the following:

- 180 ■ Let $q = 2 \max\{|U|, |V|, |W|\}$, and let the target sum be $t = 19q^6$.
- 181 ■ Map each edge (u_i, w_k) to $2q^6 + iq - k \in A$.
- 182 ■ Map each edge (v_j, w_k) to $7q^6 + jq^2 + k \in B$.
- 183 ■ Map each edge (u_i, v_j) to $t - (9q^6 + jq^2 + iq) = 10q^6 - jq^2 - iq \in C$.

184 The lemmas in [10] show that all the integers in A , B , and C are distinct (i.e., we have a
 185 valid instance of Numerical 3DM with Distinct Integers); and that any triple summing
 186 to t consists of one element each from A , B , and C , with the elements corresponding
 187 to a triangle in the graph. Thus we obtain a bijection between triangle partitions and
 188 Numerical 3DM solutions, i.e., the reduction is parsimonious.

189 **4. Numerical 3DM with Distinct Integers \rightarrow 3-Partition with Distinct Integers:**
 190 We use standard techniques to relate these problems. Convert each integer a_i , b_i , and c_i

² Their problem “1-EX3MONOSAT” is Positive 1-in-3SAT with the additional constraint that every clause has exactly three literals. Their reduction is also planarity preserving, so chaining with their parsimonious reduction from 3SAT to Planar 3SAT, we obtain that Planar 1-in-3SAT is also ASP-complete.

■ **Figure 3** Reduction from Positive 1-in-3SAT to Tripartite Edge-Disjoint Triangle Partition.

191 in Numerical 3DM to integers $8a_i + 1$, $8b_i + 2$, and $8c_i - 3$, respectively, in 3-Partition;
 192 and convert t to $8t$. In particular, all integers are still distinct, because we scale up by a
 193 factor of 8 and then shift values by less than 4. Furthermore, working modulo 8, every
 194 triple of integers summing to t must take exactly one a_i , one b_j , and one c_k . Therefore
 195 we have a parsimonious reduction.

196 Composing these reductions, we obtain that 3-Partition with Distinct Integers, and
 197 Numerical 3DM with Distinct Integers, are ASP-hard. Both problems are NP search
 198 problems, so they are ASP-complete. ◀

4 Tetris with Two Piece Types

199
 200 In this section, we will prove that for any size-2 subset $A \subseteq \{ \text{cyan bar}, \text{yellow square}, \text{purple T}, \text{green L}, \text{red L}, \text{blue L}, \text{orange L} \}$, Tetris clearing with SRS is NP-hard, and the corresponding counting problem is
 201 #P-hard, even if the sequence of pieces given to the player only contains the piece types in
 202 A . We will also show that some of the reductions work under the “hard drop only” model
 203 and the “20G” model. Refer to Table 1 for a table of all of our results.
 204

205 All of our reductions are from 3-Partition with Distinct Integers and are in the same
 206 flavor as the reduction for clearing 3-tris with rotation as given in the Total Tetris paper [7],
 207 which we will use some terminology from. In particular, the reductions will involve a starting
 208 board involving $\frac{n}{3}$ structures, which we will call “*bottles*”, of equal height of $\Theta(t \cdot \text{poly}(n))$,
 209 spaced sufficiently far apart so that bottles do not interact with each other except for line
 210 clears, and possibly along with an additional structure, which we will call a “*finisher*”, to
 211 the right of the rightmost bottle.

212 Each bottle consists of a neck portion with n constant-sized “*top segments*”, a body
 213 portion with $t \cdot \text{poly}(n)$ -sized “*units*”, and possibly $O(n)$ extra lines either above the neck
 214 portion, between the “top segments”, between the neck portion and the body portion, and/or

12:8 Tetris with Few Piece Types

215 below the body portion that get cleaned up after the rest of the lines. To simplify our
 216 arguments, we make the size of each unit larger than the size of the neck portion.

217 The finisher will be a structure that specifically prevents the rows in the body portion
 218 from clearing before all of the top segments are cleared, and is located in same rows as
 219 the body portion of the bottles when required. We will use three types of finishers, a  finisher,
 220 an  finisher (which is a vertically symmetric version of the  finisher), and a
 221  finisher, shown in Figure 4. Note that the finishers can be adapted to any number of
 222 rows larger than 4, and there is exactly one way to clear each type of finisher.

 **Figure 4** The  and  finishers (the  finisher can be obtained by reflecting the  finisher through a vertical line), and an example of the  finisher next to a bottle (in the ,  setup).

223 For each element $a_i \in A$, we create a sequence of pieces S_i , which can be decomposed
 224 into three subsequences:

- 225 ■ **Priming sequence:** A piece sequence that, if used correctly, properly blocks all bottles
 226 but one in the same “top segment”, and if used incorrectly, either directly “overflows” the
 227 bottle (i.e., puts blocks above the line under which all of our pieces must go) or “clogs”
 228 the bottle (i.e., improperly blocks the bottle and prevents the player from being able to
 229 clear the lines necessary to re-open the bottle). For all of the bottle structures except
 230 for the one for $\{\text{yellow square}, \text{purple T-shaped finisher}\}$, the pieces in the priming sequence cannot rotate or translate
 231 below the topmost “top segment” under SRS, and any piece placed into a “top segment”
 232 of a bottle prevents any piece in the filling sequence from reaching the body portion of
 233 that bottle.
- 234 ■ **Filling sequence:** A piece sequence of length $\Theta(a_i)$ that “fills” a_i units in the body
 235 portion of the unblocked bottle. If there are not enough units left to fill, then the pieces
 236 corresponding to one of the units will cause an overflow due to there not being enough
 237 empty space in the neck portion for all of the pieces (using the fact that the size of each
 238 unit is larger than the size of the neck portion).
- 239 ■ **Closing sequence:** A piece sequence that properly clears the lines corresponding to the
 240 “top segment” blocked by the priming sequence and resets the states of the neck portion
 241 of the bottles (albeit with one less “top segment”).

242 We also have a **finale sequence** F , possibly the empty sequence, which helps clear any
 243 finishers on the board and the remaining lines on the board after the lines corresponding to

244 the neck and body portions have been cleared.

245 In this section, when we write a sequence of pieces, we will use parentheses around
 246 sequences, commas between different piece types, and exponentiation to denote repeated
 247 pieces of the same piece type. For example, a sequence written as $(\text{purple } 2, \text{yellow } 3, \text{green})$ consists
 248 of 2 purple s, 3 yellow s, and an green , in that order. The sequence of pieces given to the player will
 249 be of the form $(S_1, S_2, \dots, S_n, F)$.

250 4.1 General Argument

251 We provide a very general argument for why these reductions work. If there exists a valid
 252 3-partition $(D_1, \dots, D_{n/3})$ for $\{a_1, a_2, \dots, a_n\}$, then for each S_i , determine the corresponding
 253 j_i such that $a_i \in D_{j_i}$, then use the priming sequence to block all bottles properly except for
 254 the (j_i) th one, the filling sequence to fill a_i units in the body portion of the (j_i) th bottle,
 255 and the closing sequence to reset the states of the neck portion of the bottles. After all the
 256 S_i are used in this way, all lines corresponding to the “top segments” will be cleared as there
 257 are n such “top segments” with each S_i clearing exactly one of them, and each bottle will be
 258 filled to exactly t units. Thus, in the case where there are no pieces in the finale sequence,
 259 the lines corresponding to the body portions of the bottles will be cleared, meaning that
 260 no lines remain and we have cleared the board, and in the case where there are pieces in
 261 the finale sequence, the only lines that remain are those that can be cleared by the finale
 262 sequence. Thus, the sequence $(S_1, S_2, \dots, S_n, F)$ can clear the board.

263 Conversely, if the sequence $(S_1, S_2, \dots, S_n, F)$ can clear the board, then we claim that
 264 there is a corresponding 3-partition for $\{a_1, a_2, \dots, a_n\}$. In particular, for each S_i , the
 265 priming sequence must properly block all but one bottle, say the (j_i) th bottle, forcing all
 266 the pieces in the filling sequence into the (j_i) th bottle. The filling sequence must then fill
 267 exactly a_i units in the (j_i) th bottle before the closing sequence, and it must do so without
 268 overfilling the body portion of the bottle, as otherwise there will be an overflow in that
 269 bottle. In particular, this means that, for each $1 \leq j \leq \frac{n}{3}$, the sum of the a_i corresponding
 270 to the S_j that filled some units in the j th bottle must be at most t . However, since $\sum a_i$ is
 271 exactly $t(\frac{n}{3})$, the sum of the a_i corresponding to the S_j that filled some units in the j th
 272 bottle must actually be exactly t . In other words, there is a way to partition the a_i into $\frac{n}{3}$
 273 subsets $D_1, \dots, D_{n/3}$ such that the sum of the elements in each subset is t . Thus, there is a
 274 corresponding 3-partition for $\{a_1, a_2, \dots, a_n\}$.

275 This general argument shows how YES instances of the two problems (3-Partition with
 276 Distinct Integers, Tetris clearing with SRS and restricted piece types) are equivalent, and
 277 hence that this reduction works. The rest of the subsections in this section show the bottle
 278 structures for each size-2 subset of piece types. Due to space constraints, we omit detailed
 279 construction-specific explanations; refer to the full version of our paper for more details.

280 4.2 Subsets with Pieces

281 First we show how the reduction in the Total Tetris paper [7] can be easily adapted to any
 282 subset of pieces with  pieces plus an additional piece type:

283 ► **Proposition 6.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 284 *problem is #P-hard, even if:*

285 ■ *The type of pieces in the sequence given to the player is restricted to any of $\{\text{cyan } 2 \times 2, \text{blue } L\}$,*
 286 *$\{\text{cyan } 2 \times 2, \text{orange } 2 \times 2\}$, $\{\text{cyan } 2 \times 2, \text{yellow } 2 \times 2\}$, $\{\text{cyan } 2 \times 2, \text{green } 2 \times 2\}$, $\{\text{cyan } 2 \times 2, \text{purple } 2 \times 2\}$, or $\{\text{cyan } 2 \times 2, \text{red } 2 \times 2\}$,*

12:10 Tetris with Few Piece Types

287 ■ The model being considered is “hard drops only” and type of pieces in the sequence
 288 given to the player is restricted to any of { ,  }, { ,  }, { ,  }, or
 289 { ,  }, or

290 ■ The model being considered is “20G” and the type of pieces in the sequence given to the
 291 player is restricted to either { ,  } or { ,  }.

292 Refer to Figure 5 for the bottle structures.

■ **Figure 5** The bottle structures for the subsets containing , including how the non- piece must block a bottle during the priming and closing sequence.

293 4.3 Other Subsets with Pieces

294 We now move on to all the remaining subsets which contain  pieces.

295 ► **Proposition 7.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 296 *problem is #P-hard, even if the type of pieces in the sequence given to the player is restricted*
 297 *to either { ,  } or { ,  }.*

298 Refer to Figure 6a, which shows the bottle structure for { ,  }. The bottle structure
 299 for { ,  } can be obtained by reflecting the bottle structure for { ,  } through a
 300 vertical line. We will also use a  (or ) finisher in our setup to prevent rows in the
 301 body portion from clearing early.

302 A demo of the { ,  } bottle structure can be found at jstris.jezevec10.com/map/80188.

303 ► **Proposition 8.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 304 *problem is #P-hard, even if the type of pieces in the sequence given to the player is restricted*
 305 *to either { ,  } or { ,  }.*

306 Refer to Figure 6b, which shows the bottle structure for { ,  }. The bottle structure
 307 for { ,  } can be obtained by reflecting the bottle structure for { ,  } through a
 308 vertical line. We do not use a finisher in our setup.

309 A demo of the { ,  } bottle structure can be found at jstris.jezevec10.com/map/81818.

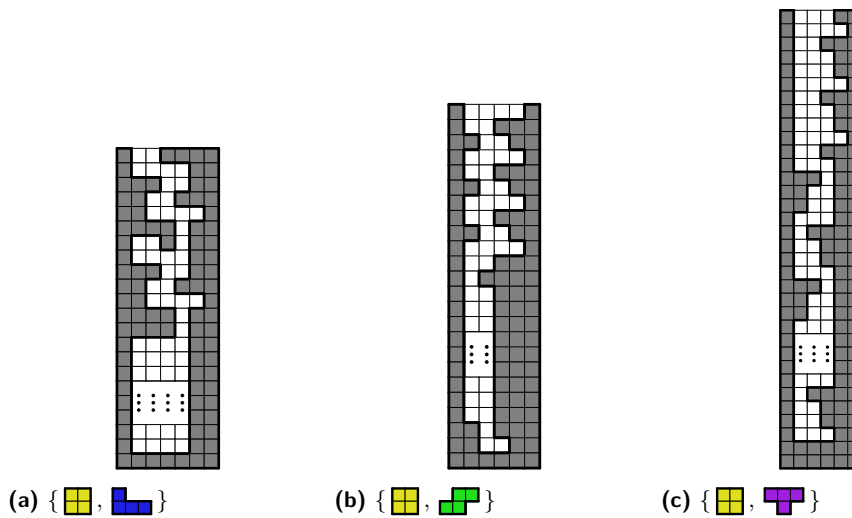

Figure 6 The bottle structures for the other subsets containing \square ; the bottle structures for $\{\square, \text{orange L}\}$ and $\{\square, \text{red Z}\}$ can be obtained by reflecting the bottle structures for $\{\square, \text{blue L}\}$ and $\{\square, \text{green Z}\}$ through a vertical line.

310 ▶ **Proposition 9.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 311 *problem is #P-hard, even if the type of pieces in the sequence given to the player is restricted*
 312 *to $\{\square, \text{purple T}\}$.*

313 Refer to Figure 6c for the bottle structure. We will also use a purple T finisher in our setup
 314 to prevent rows in the body portion from clearing early.

315 A demo of the $\{\square, \text{purple T}\}$ bottle structure can be found at jstris.jezevec10.com/map/80169.

316 4.4 Two-Element Subsets of $\{\text{green Z}, \text{purple T}, \text{red L}\}$

317 ▶ **Proposition 10.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 318 *problem is #P-hard, even if the type of pieces in the sequence given to the player is restricted*
 319 *to either $\{\text{green Z}, \text{purple T}\}$ or $\{\text{purple T}, \text{red L}\}$.*

320 Refer to Figure 7a, which shows the bottle structure for $\{\text{green Z}, \text{purple T}\}$. The bottle structure
 321 for $\{\text{purple T}, \text{red L}\}$ can be obtained by reflecting the bottle structure for $\{\text{green Z}, \text{purple T}\}$ through a
 322 vertical line. We do not use a finisher in our setup.

323 A demo of the $\{\text{green Z}, \text{purple T}\}$ bottle structure can be found at jstris.jezevec10.com/map/80184.

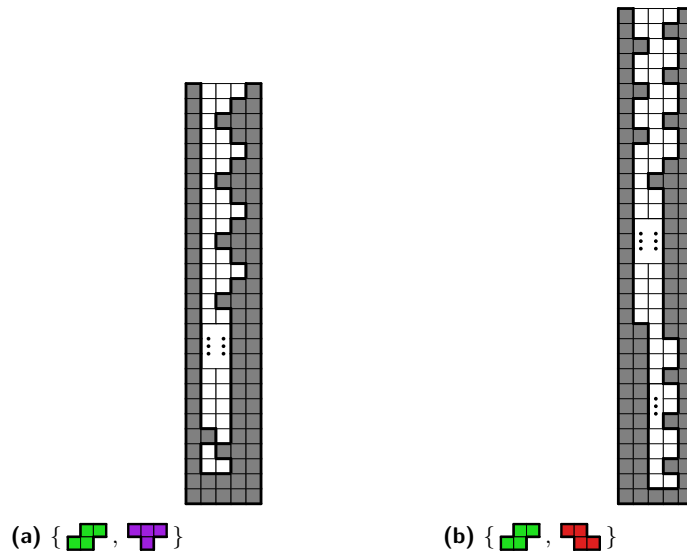

324 ▶ **Proposition 11.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 325 *problem is #P-hard, even if the type of pieces in the sequence given to the player is restricted*
 326 *to $\{\text{green Z}, \text{red L}\}$.*

327 Refer to Figure 7b for the bottle structure. We do not use a finisher in our setup.

328 A demo of the $\{\text{green Z}, \text{red L}\}$ bottle structure can be found at jstris.jezevec10.com/map/80198.

329 4.5 Remaining Subsets with More Complex Structures

330 ▶ **Proposition 12.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 331 *problem is #P-hard, even if the type of pieces in the sequence given to the player is restricted*
 332 *to any of $\{\text{blue L}, \text{purple T}\}$, $\{\text{blue L}, \text{red Z}\}$, $\{\text{orange I}, \text{green Z}\}$, or $\{\text{orange I}, \text{purple T}\}$.*

■ **Figure 7** The bottle structures for the two-element subsets of $\{\text{green square}, \text{purple square}, \text{red square}\}$; the bottle structure for $\{\text{purple square}, \text{red square}\}$ can be obtained by reflecting the bottle structure for $\{\text{green square}, \text{purple square}\}$ through a vertical line.

333 Refer to Figure 8a, which shows the bottle structure for $\{\text{blue L}, \text{red L}\}$ and $\{\text{blue L}, \text{purple T}\}$.
 334 The bottle structure for $\{\text{orange L}, \text{green L}\}$ and $\{\text{orange L}, \text{purple T}\}$ can be obtained by reflecting the
 335 bottle structure for $\{\text{blue L}, \text{red L}\}$ and $\{\text{blue L}, \text{purple T}\}$ through a vertical line. We will also use a
 336 blue L (or orange L) finisher in our setup to prevent rows in the body portion from clearing early.
 337 A demo of the $\{\text{blue L}, \text{red L}\}$ bottle structure can be found at jstris.jezevec10.com/map/80205.

338 ► **Proposition 13.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 339 *problem is #P-hard, even if the type of pieces in the sequence given to the player is restricted*
 340 *to either $\{\text{blue L}, \text{green L}\}$ or $\{\text{orange L}, \text{red L}\}$.*

341 Refer to Figure 8b, which shows the bottle structure for $\{\text{blue L}, \text{green L}\}$. The bottle structure
 342 for $\{\text{orange L}, \text{red L}\}$ can be obtained by reflecting the bottle structure for $\{\text{blue L}, \text{green L}\}$ through a
 343 vertical line. We will also use a blue L (or orange L) finisher in our setup to prevent rows in the
 344 body portion from clearing early.
 345 A demo of the $\{\text{blue L}, \text{green L}\}$ bottle structure can be found at jstris.jezevec10.com/map/83069.

346 ► **Proposition 14.** *Tetris clearing with SRS is NP-hard, and the corresponding counting*
 347 *problem is #P-hard, even if the type of pieces in the sequence given to the player is restricted*
 348 *to $\{\text{blue L}, \text{orange L}\}$.*

349 Refer to Figure 8c(a) for the bottle structure for $\{\text{blue L}, \text{orange L}\}$. We will also use a blue L
 350 finisher in our setup to prevent rows in the body portion from clearing early.
 351 A demo of the $\{\text{blue L}, \text{orange L}\}$ bottle structure can be found at jstris.jezevec10.com/map/80195.
 352 We also note the following:

353 ► **Conjecture 15.** *The reduction in the proof of Proposition 14 works even if pieces experience*
 354 *20G gravity.*

355 4.6 Putting It All Together

356 Combining all of these results, we get the following result:

Figure 8 The bottle structures for the other subsets containing $\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}$; the bottle structure for $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$ and $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$ can be obtained by reflecting the bottle structure for $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$ and $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$ through a vertical line, and the bottle structure for $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$ can be obtained by reflecting the bottle structure for $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$ through a vertical line.

357 **▶ Theorem 16.** For any size-2 subset $A \subseteq \{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$, Tetris
 358 clearing with SRS is NP-hard, and the corresponding counting problem is #P-hard, even if
 359 the type of pieces in the sequence given to the player is restricted to the piece types in A .

360 **Proof.** Propositions 6, 7, 8, 9, 10, 11, 12, 13, and 14 cover all size-2 subsets of piece types,
 361 as shown in Table 1; combining all of the reductions, we obtain the desired result. ◀

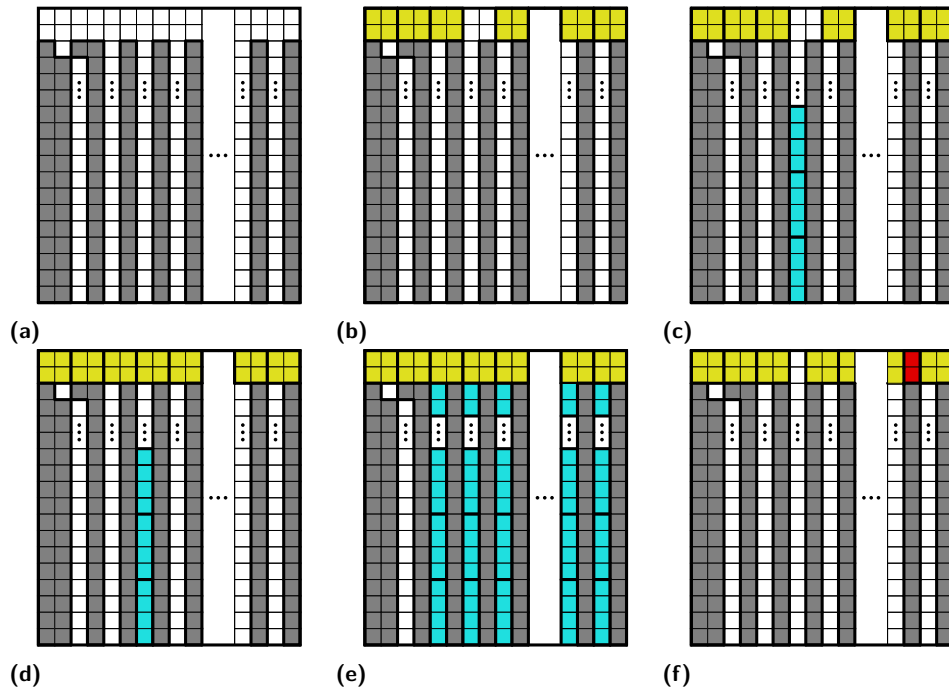

362 **▶ Remark 17.** All of our reductions involve a linear-factor blowup in the a_i for the filling
 363 sequences (i.e., we use $\Theta(na_i)$ pieces in the filling sequences); this makes it easier to argue
 364 about what happens when an overflow happens and makes the bottle analogy more fitting
 365 (since the neck portion is smaller while the body portion is much larger) but makes our
 366 reductions somewhat inefficient. Perhaps it is possible to reduce the blowup to a constant
 367 factor, though the argument may be a bit more complex.

368 5 Tetris Survival: Hard Drops Only and 20G

369 The previous section mentions NP-hardness of Tetris clearing under the “hard drops only”
 370 and “20G” Tetris models. Previous results about general Tetris [7, 2] have also proven
 371 NP-hardness of Tetris survival, so in this section, we prove that, in both of these vari-
 372 ants, Tetris survival is NP-hard using $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$ pieces. This improves upon a result by
 373 Temprano [12] which proves hardness for “hard drops only” mode using the piece subset
 374 $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$.

375 **▶ Theorem 18.** Tetris survival is NP-complete in the “hard drops only” and “20G” game
 376 modes, even if the type of pieces in the sequence given to the player is restricted to $\{\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}\}$.

377 **Proof.** We reduce from 3-Partition with Distinct Integers using a similar bottle structure to
 378 other proofs in this paper. From a 3-Partition with Distinct Integers instance, we create a
 379 setup consisting of $\frac{n}{3}$ width 1 buckets, each of height $4t$, separated by width 1 columns. In
 380 addition, we create a bucket of height $t - 1$ on the left which is blocked by a single square
 381 and has an open square on the upper left diagonal. We add one additional column on the
 382 left to obtain an even width board. We leave two rows at the top of the board empty. See
 383 Figure 9(a) for details. Each a_i is encoded by the sequence $(\begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}^{n/3+1}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix}^{a_i}, \begin{smallmatrix} \blacksquare \\ \blacksquare \end{smallmatrix})$.

■ **Figure 9** The bucket structure for “hard drops only” and “20G” Tetris modes. (b) shows how beginning sequence must block all but one bucket. (c) shows the result of a filling sequence. (d) shows how the closing sequence clears the top two rows. (e) shows a full board. (f) shows improper handling during the priming sequence.

384 The priming sequence is $(\text{■}^{n/3+1})$. Due to parity constraints, the player is forced to
 385 block all but one of the buckets using these pieces. They can choose to leave either one
 386 two-block wide gap or two one-block wide gaps in the top two rows. However, if they choose
 387 to leave one-block gaps, they will create spaces that can never be filled without overflowing
 388 the screen and causing a game loss (see the squares highlighted in red in Figure 9(f)), so we
 389 can assume that they will leave a 2×2 gap, as shown in Figure 9(b).

390 The filling sequence is (■^{a_i}) ; the ■^{a_i} pieces must be placed in the pre-selected
 391 bucket, as shown in Figure 9(c). If pieces are not placed in accordance with a correct partition,
 392 then there will at some point be an extra ■^{a_i} piece which does not fit in the open bucket.
 393 This will cause the player to lose as an ■^{a_i} piece has length 4 and cannot fit in the 2×2
 394 gap in the top 2 rows (note that no ■^{a_i} piece will stick partially out of a bucket since each
 395 bucket has a height that is a multiple of 4).

396 The closing sequence is (■) . The ■ piece can only fit in the 2×2 square formed
 397 during the priming sequence (see Figure 9(e)), and it clears the top two rows, resetting the
 398 board to the initial state, except with a somewhat more filled bucket.

399 Once the player has received the entire sequence corresponding to each number in the
 400 3-partition instance, including the final closing piece, the entire board will be full (see Figure
 401 9(e)), with the exception of the extra inaccessible bucket. Because of this, the player must
 402 have filled each of the buckets to exactly the right height, solving the 3-partition instance,
 403 otherwise they would have lost.

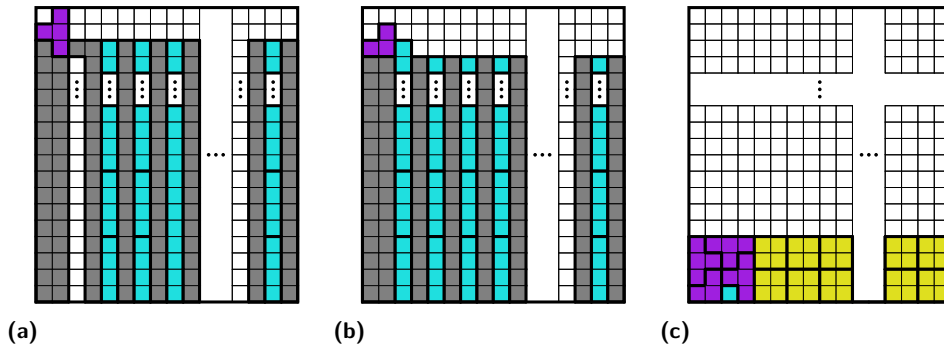

404 For the entire duration of this sequence, every piece can be hard dropped into place as
 405 there are no overhangs in any of the buckets. Furthermore, each piece can be successfully
 406 maneuvered under 20G conditions. The ■ pieces cannot fall down any buckets, so they

407 can be safely slid to any location in the top 2 rows, and the  pieces can move over the
 408 placed  pieces to the only open bucket. ◀

409 ▶ **Corollary 19.** *The above reduction can be extended to NP-hardness for board clearing*
 410 *under “hard drops only” or “20G” conditions if we also allow for  pieces.*

411 ▶ **Remark 20.** We have already proved that Tetris clearing under the “hard drops only” and
 412 “20G” models is hard with just two types of pieces. The primary reason for including hardness
 413 with a larger set of pieces is that this shows that, in both game modes, there is a board
 414 configuration and subset of pieces where the problems of surviving and clearing the board
 415 are both hard at the same time. In addition, our Tetris clearing results under the “20G”
 416 model does not include any proper subsets of $\{\text{cyan } 1 \times 4, \text{yellow } 2 \times 2, \text{purple } 2 \times 2\}$, so this result is interesting
 417 in its own right.

418 **Proof.** We begin with the above proof that survivability with $\{\text{cyan } 1 \times 4, \text{yellow } 2 \times 2\}$ is hard. We
 419 extend the sequence with the finale sequence $(\text{purple } 2 \times 2, \text{cyan } 1 \times 4^t, \text{yellow } 2 \times 2^{2n/3}, \text{purple } 2 \times 2^3)$. Figure 10 shows
 420 the clearing process. We begin by using the first  piece to open the inaccessible bucket
 421 by clearing a row. We then use the  pieces to fill the previously inaccessible bucket,
 422 clearing all but the final two rows in the process. The final  piece protrudes one square
 423 from its bucket because of the row cleared by the first . We use the  pieces to fill the
 424 $\frac{2n}{3} \times 4$ space on the right of the board. Finally, we place the remaining three  pieces to
 425 fill the remaining space and completely clear the board. All of these pieces can be placed in
 426 both special game modes. ◀

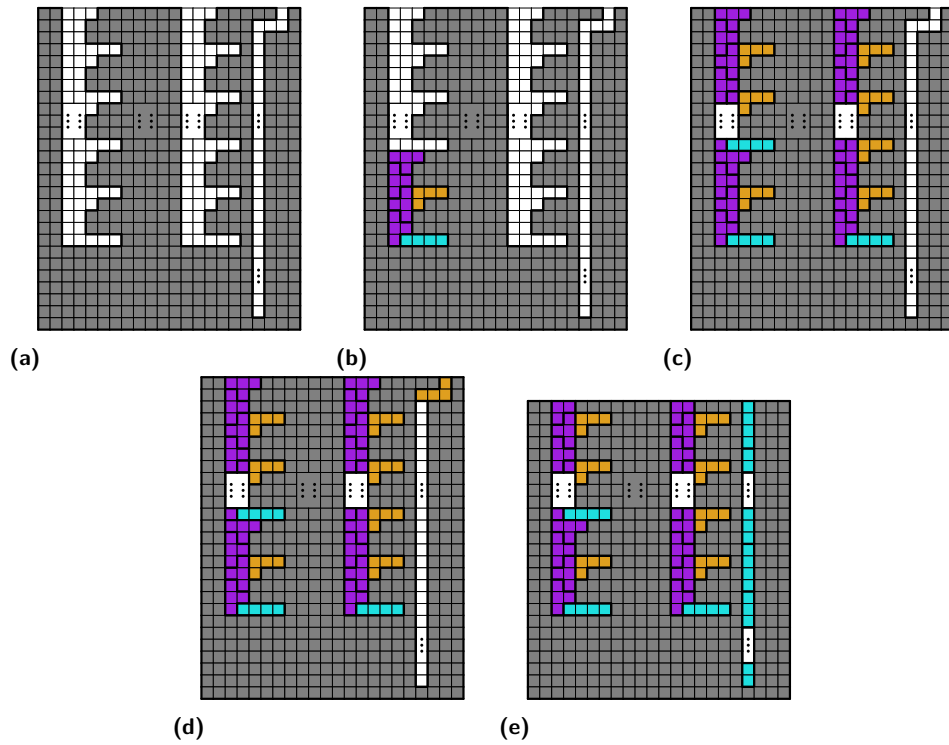

■ **Figure 10** The clearing procedure for “hard drops only” and “20G” using $\{\text{cyan } 1 \times 4, \text{yellow } 2 \times 2, \text{purple } 2 \times 2\}$

427 **6 ASP-Completeness of Tetris**

428 Even though the reductions in Section 4 are sufficient to prove #P-hardness, the reductions
 429 are not parsimonious, so they cannot be used to prove ASP-completeness. Indeed, the
 430 “blocking” bottles paradigm likely cannot be used to show ASP-completeness as there are
 431 many ways to permute the pieces that block all but one bottle. Thus, for ASP-completeness,
 432 we turn back to the “priming” buckets paradigm in [4]:

433 ▶ **Theorem 21.** *Tetris clearing with SRS is ASP-complete even if the type of pieces in the*
 434 *sequence given to the player is restricted to either $\{\text{cyan } 1 \times 4, \text{purple } 2 \times 2, \text{orange } 2 \times 2\}$ or $\{\text{cyan } 1 \times 4, \text{purple } 2 \times 2, \text{blue } 2 \times 2\}$.*

■ **Figure 11** The bucket structure plus rightmost columns for $\{\text{cyan}, \text{purple}, \text{orange}\}$. (b) shows how the cyan piece must prime a bucket (requires an cyan spin) and how the remainder of the pieces in a sequence must fit in the bucket ($m = 2$ here). (c) shows how the board looks like before the finale sequence. (d-e) show how the pieces in the finale sequence must be placed (requires an orange spin).

435 **Proof.** First we discuss the $\{\text{cyan}, \text{purple}, \text{orange}\}$ case. We give a parsimonious reduction from
 436 Numerical 3-Dimensional Matching with Distinct Integers; refer to Figure 11(a), which shows
 437 the bucket structure plus rightmost columns for $\{\text{cyan}, \text{purple}, \text{orange}\}$.

438 Here, a “unit” is the pattern that repeats every four rows. A positive integer m is encoded
 439 by the sequence of pieces $(\text{cyan}, (\text{purple}, \text{orange}, \text{purple})^{m-1}, \text{purple}, \text{purple})$. The finale sequence is
 440 $(\text{orange}, \text{cyan}^N)$, where $N = \text{poly}(nt)$ is much larger than the height of the buckets, and is
 441 used to clear the rightmost columns after the buckets have been filled.

442 In this case, the cyan piece serves as the “primer”, and must be placed as indicated
 443 in Figure 11(b) (the placement is possible due to cyan spins). The purple pieces cannot be
 444 placed in a non-primed bucket without blocking off certain holes, particularly the squares in
 445 which an cyan piece or an orange piece must be placed, and misplacing an orange piece (i.e.,
 446 putting it in a different, non-primed bucket, putting it where the orange piece goes during the
 447 finale sequence, or putting it too high in the bucket) causes the next two purple pieces to block
 448 off squares in which an cyan piece or an orange piece must be placed. Thus, once the cyan
 449 piece is placed in a bucket, the placements of the rest of the pieces encoding the positive
 450 integer m are forced. Further discussion on and figures for improper piece placements can be
 451 found in the full version of our paper.

Lastly, to make the reduction parsimonious, from the instance

$$A = \{a_1, a_2, \dots, a_n\}, B = \{b_1, b_2, \dots, b_n\}, \text{ and } C = \{c_1, c_2, \dots, c_n\}$$

452 of Numerical 3-Dimensional Matching with Distinct Integers, we scale the a_i , b_i , and c_i and

453 add/subtract constants such that each group must consist of exactly one a_i , one b_j , and
 454 one c_k (i.e., no group with at least two elements from any of A , B , or C can sum to the
 455 target sum). In addition, we “pre-fill” all of the buckets so that the i th bucket from the left
 456 is already filled up to a_i units, and the sequence of pieces given to the player consist only
 457 of the pieces in the b_i sequences, the pieces in the c_i sequences, and the pieces in the finale
 458 sequence. This ensures that the subsets have a fixed ordering and must consist of exactly one
 459 a_i , one b_j , and one c_k . Combined with the fact that all the piece placements after each 
 460 piece in a sequence encoding a positive integer are forced, this means that each solution to
 461 the Numerical 3-Dimensional Matching instance corresponds to exactly one way to clear the
 462 Tetris board, and vice versa.

463 Therefore, we have a parsimonious reduction from Numerical 3-Dimensional Matching
 464 with Distinct Integers to Tetris clearing with $\{\text{cyan 1x4}, \text{purple 2x2}, \text{orange 2x2}\}$, meaning that Tetris clearing
 465 with SRS is ASP-complete even if the type of pieces in the sequence given to the player is
 466 restricted to $\{\text{cyan 1x4}, \text{purple 2x2}, \text{orange 2x2}\}$.

467 We get a similar argument for $\{\text{cyan 1x4}, \text{purple 2x2}, \text{blue 2x2}\}$ by vertical symmetry; the  spin
 468 required still works when mirrored even though the kick tests for  are not vertically
 469 symmetric. ◀

470 Demos of the bucket structure can be found at jstris.jezevec10.com/map/80170 for
 471 $\{\text{cyan 1x4}, \text{purple 2x2}, \text{orange 2x2}\}$ and at jstris.jezevec10.com/map/83325 for $\{\text{cyan 1x4}, \text{purple 2x2}, \text{blue 2x2}\}$.

472 **7** Open Problems

473 One big open problem that still remains is the computational complexity of Tetris clearing
 474 with SRS if the player is only given one piece type (for example, if the sequence consists
 475 of entirely  pieces). In this case, the “blocking” bottles paradigm no longer works,
 476 because the same piece type cannot be used both to block and to fill bottles without the
 477 reduction breaking, so a proof of hardness would involve an entirely different setup. It is also
 478 possible that Tetris clearing with SRS and with only one piece type is in P. For example, [4]
 479 conjectures polynomial time for the  piece type.

480 Similarly, it is open whether or not Tetris clearing with SRS is ASP-complete for subsets
 481 of pieces that are not supersets of $\{\text{cyan 1x4}, \text{purple 2x2}, \text{blue 2x2}\}$ or $\{\text{cyan 1x4}, \text{purple 2x2}, \text{orange 2x2}\}$. One could likely
 482 construct similar structures for other 3-piece subsets, but arguing whether Tetris clearing
 483 with SRS is ASP-complete for 1- or 2-piece subsets may require different ideas.

484 Some open questions arise regarding whether our results can be extended if we consider
 485 different objectives or add additional features. For example, can we establish results for
 486 2-piece subsets, similar to those in Section 4, for Tetris survival? If we add a “holding”
 487 function, where the player can put one piece aside for later use, can get similar results?

488 Modern variants of Tetris also use different random generators to ensure that the player
 489 doesn’t receive the same piece arbitrarily many times in a row. One of the simplest random
 490 generators is called a *7-bag randomizer*. For this randomizer, the sequence of pieces is
 491 divided into groups (or “bags”) of 7, each group containing one of each tetromino in one of
 492 $7! = 5,040$ possible orderings. Can we show NP-hardness even if the sequence of pieces has
 493 to be able to be generated from this randomizer?
